FIG. 4

The flowchart illustrates the auction process, starting with the 'Domain of a Static Online Catalog' which contains 'Inventory Item Description', 'Sales and Inventory Records', and a 'Standard Static Catalog system'. The process begins with a 'Sales pattern Criteria watcher' (which can dynamically set start price for Auction) and a decision 'Are Criteria for Auction Conversion Satisfied?'. If 'No', it loops back to the 'Standard Static Catalog system'. If 'Yes', it proceeds to 'Activate Automated Auction and wait for it to return its location (pointer, hyperlink, or other locator)'. This leads to 'Replace Standard Sale controls in Static Auction with Link to Live Auction (open invitation)', which then connects to the 'Live Auction' system. The 'Live Auction' system includes a 'Live Auction Location' and a 'Live Auction takes control of All Auction Data' step. It also receives 'Item Inventory Details' and sends data back to the 'Standard Static Catalog system'. The 'Live Auction' system then triggers the 'Messaging Dispatch System'. A decision 'Is bidder logged on to system?' follows. If 'Yes', it leads to 'Notify Bidder via Local Message'. If 'No', it leads to 'Format Message for chosen messaging system', which then connects to 'Dispatch invitation via preferred messaging system'. This step branches into 'E-Mail', 'Instant Messaging', and 'Other (Pager, Interactive TV, etc)'. A decision 'Has list been completed?' follows. If 'No', it loops back to the 'Messaging Dispatch System'. If 'Yes', it leads to 'Wait for notification from real-time auction of completion of the auction'. This step then connects to 'Contact Static Sale system Remove UI for entering Real-time Auction Provide final sales info to Static System for records'. Finally, the process ends with 'Finish Data and Storage Clean up Conversion is completed'.
